

Tsenta: AI-Powered Job Application Platform

Tsenta is a Y-Combinator-backed AI agent that automates job searching and applications. It **monitors tens of thousands of company career pages** (Workday, Greenhouse, Lever, Ashby, etc.) and matches roles to your resume. When a suitable job appears, Tsenta uses AI to rewrite your résumé and cover letter for that role and then auto-fills the application form on the employer’s site. The system spans four stages: **Find** (scan jobs), **Prep** (tailor application), **Apply** (submit via ATS), and **Track** (route recruiter replies). For example, Tsenta’s web dashboard displays matched jobs with fit scores and tracks application statuses (see figure)

The screenshot displays the Tsenta dashboard interface. On the left is a sidebar with navigation links: Dashboard, Browse jobs, Applications (387), Inbox (113), Tracker, Profile, and Settings. The main area is titled 'Dashboard' and features a search bar 'Search by title, company...'. Below the search bar are filters for Date, Role, Job Type, Workplace, Location (selected), Max Experience, and More. There are buttons for 'Apply', 'Add your own', 'Browse jobs', and 'Apply to all 5'. The 'Top job matches' section shows five job cards with fit scores: Software Development Engineer 4 (72% match), AI Platform Engineer (72% match), Lead Software Engineer - Backend (71% match), Senior Manager Software Engineering... (71% match), and Engineer, Software (71% match). Each card includes the company logo and an 'Apply' button. The 'All applications' section shows a summary of application status: All 387, Submitted 210, In flight 0, Needs you 2, Failed 14, Skipped 79. Below this is a table with columns: COMPANY, RESUME, COVER LETTER, STATUS, and APPLIED. The table lists five applications with their respective company names, resume status, cover letter status, submission status, and time applied.

COMPANY	RESUME	COVER LETTER	STATUS	APPLIED
AT Allen Technology USA Lead Full Stack Software Engineer	Ready	Ready	Submitted	4 hours ago
AS Asurion Senior Software Engineer	Ready	Ready	Submitted	4 hours ago
RB Restaurant Brands International Sr. Software Engineer, Popeyes	Ready	Ready	Submitted	4 hours ago
RC Rocket Companies Principal Software Engineer	Ready	Ready	Submitted	4 hours ago
AL Alphasense Senior Staff Software Engineer	Ready	Ready	Submitted	4 hours ago

Users can review each AI-generated resume/cover change before submission, and Tsenta shows a “receipt” of each completed application. Overall, Tsenta promises “full automation” at high volume: its plans (e.g. 600–4500 applications/month) are priced by credits used, not by time.

Figure: Tsenta's dashboard and job feed interface (from Tsenta blog). Left: Dashboard showing matched jobs and current pipeline counts. Right: Application Tracker showing queued/submitted roles by company and status. Users browse jobs ("Apply" buttons with match %), queue applications, and see confirmations.

User Flow: Onboarding to Application

- **Sign-up & Profile Setup:** The user creates an account, enters basic info, and uploads their résumé (or LinkedIn profile). Tsenta also gathers work preferences (roles, locations, etc.) and may use an initial survey or resume parsing. (Tsenta's docs imply a conversational signup via web, iMessage/WhatsApp, or CLI.)
- **Job Matching:** Tsenta continuously scans 50,000+ career pages. As soon as a new job post matches the user's profile, Tsenta notifies them (hours before ATS see it). Jobs are scored by relevance (resume similarity, keywords, skill requirements).
- **Review & Approval (Prep):** When a match is found, Tsenta drafts a customized résumé and cover letter for that specific role (drawing on the job description and user profile). It shows a **diff view** of changes for the user to edit or approve. The user can explicitly "approve & send" or it auto send after 2-3 sec.
- **Automated Apply:** Upon approval, Tsenta's automation engine opens the employer's ATS form (Workday, Greenhouse, Lever, Ashby, etc. – Tsenta covers 12 major platforms) and fills every field (login, personal info, resume upload,

questionnaire answers) using the tailored content. The user watches the form fill happen in real time (Tsenta can operate fully headless or with an overlay) and then hits submit. A digital “receipt” of the submission is immediately shown.

- **Tracking (Post-Apply):** After submission, Tsenta “auto-routes” recruiter emails and status updates back into the app’s inbox pipeline. Replies, interview invites, and rejections are linked to the right application and advance the status automatically (so the user’s inbox becomes a structured pipeline). The user can see which roles are “*In flight*”, “*Needs you*” (e.g. if additional info is required), “*Submitted*”, etc., all in the Dashboard.
- **Payment & Credits:** Tsenta uses a credit-based subscription model. New users get a free trial (e.g. 25 free applies), then choose a plan or buy credit packs. Each successful application consumes one credit. Tsenta emphasizes “you pay for applications, not the tool”.

Technology Stack and Architecture

Tsenta’s publicly disclosed stack combines modern web/mobile frontends with AI and browser automation:

- **Front-end Applications:** Tsenta provides an interactive **web dashboard** (built with React and TypeScript). In fact, Tsenta’s own materials note “distributed React+TS surfaces” serving millions of users. Users see job feeds, edit resumes, and track applications in the web UI. In addition, Tsenta has a **Chrome extension** (to enable applying from any job page on the web), native **desktop apps** (Mac/Windows/Linux, likely Electron) and mobile apps (Android and iOS). It also offers a conversational interface: an **iMessage/WhatsApp bot** for apply-by-text, and a CLI/MCP interface for AI assistants (like Claude).
- **AI Services:** A core part of Tsenta is its AI engine. It uses Large Language Models (Anthropic’s Claude Code and OpenAI’s GPT) for multiple tasks: *job matching*, *résumé rewriting*, and answering open-text screening questions in the user’s voice. For each matched job, Tsenta’s LLM tailors the resume and cover letter (with keyword alignment) and drafts answers to open-ended questions. It then ensures all changes are transparent (shown as diff) before submission. Anthropic and OpenAI are explicitly named as AI providers in Tsenta’s docs.
- **Application Automation:** To actually submit applications, Tsenta runs a **headless browser/automation engine**. It logs into the target ATS, navigates multi-page forms, auto-fills fields (including dynamic drop-downs, file uploads, and OTPs), and clicks submit. Tsenta claims to handle login flows and “every field” on a form. If an OTP or extra verification is needed (e.g. email code), Tsenta can detect it via limited email access. (Their privacy policy explains a secure OAuth integration to scan only OTP emails and autofill codes.)

- **Backend Infrastructure:** The core backend likely runs on cloud containers with a managed database. In its privacy policy, Tsenta reveals it is hosted on **Fly.io** with managed PostgreSQL, fronted by **Cloudflare** for CDN and DDoS protection. Firebase (Google) is used for user authentication and session management. Monitoring/analytics use tools like PostHog/Sentry, and transactional email via AWS SES/Resend. (These choices suggest a containerized, microservices architecture – e.g. Docker services on Fly.io — with a mix of Node/Python services behind the scenes.)
- **Databases and APIs:** User data (accounts, profiles, resumes, application records) are stored in the Postgres DB. Tsenta also integrates with external services: it connects to email accounts via OAuth (using Composio) to read OTPs, and routes data through MCP (Model Context Protocol) when connected to an AI assistant. All inter-service communication is secured, and only minimal data (resume text, job info) is passed through the AI providers.
- **Payment System:** For billing, Tsenta uses a provider called **Dodo Payments** for subscriptions and credit pack purchases. (In Pakistan, a similar system could use Stripe or a local gateway with credit-card or mobile payments.)
- **Security:** Tsenta operates over HTTPS and uses industry-standard safeguards. Data at rest is encrypted in the managed database. The privacy policy affirms “reasonable technical, administrative, and physical safeguards”. Email integration uses limited scopes (only OTP extraction, no full inbox access). They mention a bug-bounty program for vulnerability reporting. Overall, infrastructure like Cloudflare provides DDoS protection, and services like Fly.io handle OS-level security.

Infrastructure & Deployment

Tsenta’s approach suggests a **scalable cloud deployment**. The job-scanning agents would run in parallel workers (e.g. Kubernetes or Fly.io services) polling career pages 24/7. Each job posting triggers pipelines for matching and application. The web dashboard is a React SPA served from a CDN (likely via Cloudflare). A typical workflow might involve message queues: e.g. a job-fetch service finds new postings, publishes to a queue, and worker processes invoke the AI tailoring and browser automation. The database must track user profiles, queued applications, and status updates.

For global scaling, Tsenta’s choice of Fly.io is instructive (it offers multi-region container hosting). One could similarly use AWS ECS/EKS or Google Cloud Run. The use of managed Postgres means automatic backups and replication. Cloudflare ensures fast delivery worldwide and shields against attacks. OAuth and TLS ensure secure user sessions. For development, continuous integration/deployment pipelines would push Docker images to Fly.io (or Kubernetes clusters).

Key architecture points: Tsenta splits trust by design: heavy AI and scraping work runs on its servers, but **all user-specific changes** (résumé edits) are explicitly shown to the user before submission. This hybrid on-device/cloud model helps with trust – a user’s raw data is not blindly sent to recruiters. (Tsenta’s own site states the app “runs on your device” to give users control, even though most processing happens in the cloud.)

User Feedback and Weaknesses

Public feedback is still limited, but a few patterns emerge. Users appreciate that Tsenta emphasizes **relevance and control** over mere volume. One review noted Tsenta “focuses on profile, communication, and whether you fit the role instead of just spamming resumes”. This aligns with Tsenta’s stance that irrelevant “spray-and-pray” bots hurt serious candidates.

However, commenters also point out caveats. Tsenta isn’t “instant” like a simple LinkedIn autofill; it waits for actual company postings, so it may not find quick wins on boards. In practice, a user said Tsenta “works well” but “not ideal if you want instant results”. Another risk (common to all auto-apply tools) is flooding employers with generic applications: one Reddit commenter warned that many bots merely inflate numbers to extract subscription fees, often burying genuine applicants. Tsenta counters this by strict matching and requiring user approval of content, but the concern remains that too many automated apps could train recruiters to ignore such traffic.

Trust and transparency were critical issues early on. Tsenta’s founders reported initial users reacted negatively to hidden automation (“it looks like a virus”). In response, Tsenta rebuilt its architecture: *every* change is now visible and editable, and they emphasize that nothing is “blind” or sent without approval. This highlights a general vulnerability: if users ever feel out of control, they will abandon the tool. Thus **usability and trust** are as important as raw automation power.

Other potential weak points: Tsenta’s coverage is limited to certain ATS platforms. Any roles posted outside those (e.g. via email, small boards, or LinkedIn only) won’t be seen. Tsenta’s pricing model (pay per apply) could also backfire if users don’t get interviews, though its blog contrasts favorably with costlier competitors. Finally, maintaining the scraping logic is a constant challenge: ATS websites change often, so Tsenta must continually update its automation scripts.

Competitive Analysis of Tsenta and Similar Products

Product	Pricing (approx.)	What It Actually Does	Mode of Apply	Biggest Strength	Biggest Weakness	User Sentiment
Tsenta	Free trial of 25 applications, then \$19/\$39/\$99 per month depending on application credits	End-to-end job automation: discovers jobs, tailors resume, fills forms, submits applications, tracks status	Desktop app + Web + MCP/AI agent integrations	True ATS submission, real-time browser automation, supports many ATS systems	Primarily ATS-focused; less useful for Google Forms and non-standard hiring workflows	Users like the transparency of seeing applications happen in real time. (Tsenta)
JobCopilot	Roughly \$28–32/month depending on plan	AI finds jobs and auto-applies on company sites, includes resume builder and interview tools	Web app	Finds jobs automatically and can send real applications	Community reports mention quantity over quality and occasional duplicate applications	One user: "It did apply/submit my resume to around 200 employers... but the majority went to the same two staffing agencies." (JobCopilot)
AIApply	Around \$50/month for 100 applications plus add-ons	Resume builder, cover letters, auto-apply, interview preparation	Web app	Strong AI document generation and interview prep	Pricing gets expensive quickly and ATS support is not clearly documented	Generally appreciated for resume tools but criticized for pricing and upselling. (Reddit)
Simplify	Free tier, Simplify+ around \$39.99/month	Autofills applications, job tracker, networking insights,	Browser extension + Web	Excellent autofill experience and very polished UX	Does not autonomously submit applications; user still	Popular among students because it saves time without

		resume tools			clicks submit	taking control away from the user. (Simplify Jobs)
Teal HQ	\$29/month or \$79/quarter	Resume optimization, keyword matching, application tracker	Web app	One of the best resume builders and application trackers	No auto-apply capability	One user called it "the easiest way to organize all aspects of your job search." (Teal)
Sonara AI	~\$23.95/month	AI job discovery and automatic applications through partner job boards	Web app	Very simple "set and forget" experience	Primarily focused on U.S. job boards and lacks transparency into applications	Users appreciate the automation but want more control over what gets submitted. (Tsenta)
LazyApply	\$99–999/year depending on plan	High-volume applications on LinkedIn, Indeed, ZipRecruiter, Dice	Browser extension	Massive application volume	Often criticized for low-quality, generic applications and possible account risks	Users report mixed outcomes and concerns about automated mass applications. (Tsenta)

Development Roadmap and Challenges

To build a similar platform (for Pakistan or globally), one would proceed in stages:

1. **Define Scope & Market Research.** Identify target job sources. For Pakistan, this could include local job boards (Rozee.pk, Mustakbil.com) and the career pages of major Pakistani employers (banking, telecom, IT firms). Decide language/support (English or Urdu). Research user pain points and pricing tolerance.
2. **User Onboarding & Profile Module.** Develop a web/mobile front end (e.g. React) for user signup and profile creation. Allow résumé upload and form filling for background (education, skills, preferences). This data will seed matching. Ensure strong auth (e.g. Firebase or Auth0) and secure storage (users will upload resumes).
3. **Job Aggregation Engine.** Build a crawler or use APIs to collect job postings. Initially focus on a few sources (e.g. Rozee API or RSS feeds, plus major corporate ATS). Normalize job data (title, location, description). Set up a schedule to poll frequently (cron jobs or queue workers). (Tsenta scans 50K pages daily, but a startup can begin with hundreds of key sites.)
4. **Matching Algorithm.** Implement a matching/scoring system. A simple start is keyword matching and filtering (resume keywords vs job keywords). For higher quality, integrate an LLM (e.g. GPT-4 or open models) to “understand” context and score fit. Tsenta scores jobs relative to your resume and surfaces the top matches. Your platform should similarly filter out irrelevant postings to save users’ time.
5. **AI Tailoring & Approval Workflow.** Integrate an AI model to rewrite resumes/cover letters. For each job, feed the job description and user’s base resume into an LLM to generate a tailored resume and cover note. Present the changes to the user in an editable diff interface. Only after the user reviews and approves should the application proceed.
6. **Form Filling Automation.** Use a headless browser tool (like Puppeteer or Playwright) to automate applications. Write scripts for each ATS flow: log in, navigate, fill forms, upload files, answer questions. Handle two-factor steps by pausing or waiting (e.g. extract OTP from email via an OAuth email fetch, similar to Tsenta’s Composio integration). Test these flows exhaustively; many ATS have complex multi-step forms.
7. **Notifications & Tracking.** Implement an email listener and/or API polling to detect responses. If possible, ask users to authorize email access (with strict scope) to auto-detect recruiter replies or OTPs. Otherwise, have users manually input updates. Create a pipeline dashboard: show each application’s status and thread recruiter replies back to the job entry.

8. **Multi-Channel Interfaces.** After core functionality, expand to other surfaces. A mobile app (or a responsive web) and messaging integration can improve engagement. For example, allow users to approve applications via WhatsApp (using a business API) or an Android push notification. A browser extension could let users trigger the apply bot on an open job page. Even offering a CLI/AI-agent connector (MCP) could be considered for advanced users.
9. **Payment and Plans.** Integrate a payment gateway (Stripe is ideal, or local alternatives like PayFast or JazzCash in Pakistan) and set up a credit system. Mirror Tsenta's model of credit packs and monthly tiers. Be transparent about pricing. Tsenta found it important to decouple tool subscription from application cost.
10. **Deployment & Scaling.** Host the backend on a cloud provider. Tsenta's choice of Fly.io suggests a containerized approach; you could use AWS ECS/EKS or Google Cloud Run. Use managed databases (Postgres) for user and job data, and a CDN for static assets. Apply best practices: HTTPS everywhere, regular backups, and DDoS protection (e.g. Cloudflare). Set up logging/monitoring (Sentry, PostHog) to catch errors as Tsenta does.
11. **Iterate with User Feedback.** Crucial to success will be user trust. Ensure the product is transparent: *show* users exactly what changes are being made to their resume (no hidden fields). Collect feedback (e.g. a forum or chatbot) and adjust. Early Tsenta users demanded visibility ("we had to rebuild for trust"), so prioritize clear UX.

Key Challenges: Building robust web automation is hard. Each ATS may require custom scraping and often breaks (CAPTCHAs, site redesigns, etc.). Handling OTPs/email flow requires secure email access. Integrating AI means balancing quality vs. cost (LLM API calls are expensive). Trust is another hurdle: users must feel in control of their information. Also, local factors matter – e.g. if many Pakistani jobs aren't posted on big ATS, you may need to scrape local boards or even allow user-provided job links. Finally, enforcement: some sites may forbid bots; ensure compliance with terms of service or accept legal risk.

In summary, developing a "Tsenta-like" platform involves combining web/frontend development, AI/NLP models, browser automation, cloud infrastructure, and user-centric design. Citations above show Tsenta's feature set and stack, which you can use as a blueprint. A realistic roadmap starts small (few job sources, manual approvals) and gradually automates more, continuously testing with real users and iterating to build trust and stability.
